OUTLINE

INTRODUCTION

METHODOLOGY

RISK NEUTRAL APPROACH

RISK AVERSE APPROACH

EXPERIMENTS

CONCLUSION

CONTEXT

Figure: Ad exchange mechanism

PROBLEM DESCRIPTION

- ▶ An advertiser or agent (decision maker)
- ▶ Data: website users, ad slots format
- ▶ Find the optimal bidding policy given the predetermined budget for a certain period of time
- ▶ Map the bidding prices to each ad opportunity at once:
Maximize the profit;
Control the risk of violating the budget constraint.

RELATED WORK

- ▶ Linear related to Click-through rate (CTR) [11] , or value of click [10, 2] (truthful bidding)
- ▶ Non-linear with estimations of CTR, winning probabilities, etc. [16, 5, 12]
- ▶ Multi-stage: RL-based models [8, 15, 17, 4]

RISK MANAGEMENT ON PROFIT (RMP) MODEL [7]

- ▶ Static problem
- ▶ Risk of generated profit
- ▶ Risk from CTR estimation error (Bayesian logistic regression)
- ▶ Winning price is an independent variable

METHODOLOGY

- ▶ A stochastic model that mixes both empirical and parametric distributions
- ▶ Expected utility theory [1, 9] with entropic risk measure [13]
- ▶ Optimize a bid policy over a batch of M opportunities

ASSUMPTION

Assumption 1

The winning price W , realized click C and net value of the customer V are mutually independent given X .

MODELING CONDITIONAL CTR

- ▶ We assume that the CTR depends on the opportunity's features X , and formally denote ¹:

$$\theta(X) := \mathbb{P}(C|X)$$

¹DeepFM model [6] is used to estimate $\theta(X)$

MODELING CONDITIONAL WINNING PRICE DISTRIBUTION

- ▶ The winning price W is conditional on observing X
- ▶ W follows the normal distribution $W \sim N(\hat{w}(X), \sigma(X))$
- ▶ Parametrized probability distribution function of the winning price W modeled as follows ²:

$$f_{W|X}(w) = \frac{1}{\sigma(X)\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{w-\hat{w}(X)}{\sigma(X)}\right)^2}.$$

²DeepFM model [6] is used to estimate $\hat{w}(X), \sigma(X)$

MODELING CONDITIONAL WINNING PROBABILITY

- ▶ Expense only happens when the advertiser wins the bids [10]
- ▶ We model the probability of winning the bid depends on the bidding price b and the winning price W :

$$s(b, W) := 1\{b \geq W\} = \begin{cases} 1 & b \geq W \\ 0 & \text{otherwise} \end{cases}$$

MODELING CONDITIONAL VALUE OF CUSTOMER

- ▶ We model this variable conditional on the given opportunity X by³ :

$$\hat{V}(X) := \mathbb{E}[V|X]$$

³In our experiments, V will be considered independent of X and known for simplicity.

RISK NEUTRAL MODEL

- ▶ Considering a random batch of M i.i.d. opportunities denoted by $\{(X_i, W_i, C_i, V_i)\}_{i=1}^M$, with each V_i , C_i , and W_i mutually independent given X_i (as per Assumption 1)
- ▶ Maximizes the expected profit generated over the batch while satisfying the budget constraint:

$$\begin{aligned} b^{\text{rnp}}(\cdot) &:= \operatorname{argmax}_{b: \mathcal{X} \rightarrow \mathbb{R}^+} && \mathbb{E}[\text{Batch profit}] \\ &\text{s. t.} && \mathbb{E}[\text{Batch expense}] \leq BM, \end{aligned}$$

MATHEMATICAL FORM

- ▶ Based on the linearity of expectation, batch expressions can be simplified to expected instantaneous value format:

$$\begin{aligned} b^{\text{rnp}}(\cdot) = \operatorname{argmax}_{b: \mathcal{X} \rightarrow \mathbb{R}^+} & \quad \mathbb{E}[VCs(b(X), W)] - \mathbb{E}[Ws(b(X), W)] \\ \text{s. t.} & \quad \mathbb{E}[Ws(b(X), W)] \leq B. \end{aligned} \tag{1}$$

MODEL THE RISK

- ▶ Exponential utility function to model the risk aversion
- ▶ We replace the expected expense constraint with:

$$\mathbb{E}[u_\alpha((1/M)\text{Batch expense})] \geq u_\alpha^{-1}(B),$$

where $u_\alpha(y) := -\exp(\alpha y)$ is a concave utility function that allows the decision maker to control risk exposure using the parameter α .

MODEL THE RISK

- ▶ For a batch of M opportunities, the constraint takes the form:

$$\mathbb{E}\left[u_\alpha\left(\frac{1}{M} \sum_{i=1}^M W_i s(b(X_i), W_i)\right)\right] \geq u_\alpha(B). \quad (2)$$

MODEL THE RISK

Lemma 1

Constraint (2)

$$\mathbb{E}[u_\alpha(\frac{1}{M} \sum_{i=1}^M W_i s(b(X_i), W_i))] \geq u_\alpha(B)$$

is equivalent to

$$\mathbb{E}[h(b(X), X)] \geq -1,$$

where

$$h(b, X) := -e^{\gamma_1(X)} \Phi\left(\frac{b - \hat{w}(X) - \alpha' \sigma(X)^2}{\sigma(X)}\right) - e^{\gamma_2} + e^{\gamma_2} \Phi\left(\frac{b - \hat{w}(X)}{\sigma(X)}\right) \quad (3)$$

with $\alpha' := \alpha/M$, $\gamma_1(X) := (1/2)(\alpha')^2 \sigma(X)^2 + \alpha' \hat{w}(X) - \alpha' B$ and $\gamma_2 := -\alpha' B$.

RISK AVERSE PROFIT MAXIMIZATION MODEL

- The risk-averse expected instantaneous profit maximization problem:

$$\begin{aligned} b^{\text{rap}}(\cdot) := \operatorname{argmax}_{b: \mathcal{X} \rightarrow \mathbb{R}^+} & \quad \mathbb{E}[VC_s(b(X), W)] - \mathbb{E}[W_s(b(X), W)] \\ \text{s. t.} & \quad \mathbb{E}[h(b(X), X)] \geq -1. \end{aligned} \tag{4}$$

LAGRANGIAN RELAXATION

$$\begin{aligned}\tilde{b}_\lambda^{\text{rap}}(\cdot) &:= \operatorname{argmax}_{b:\mathcal{X}\rightarrow\mathbb{R}^+} \mathbb{E}[VCs(b(X), W)] - \mathbb{E}[Ws(b(X), W)] \\ &\quad - \lambda(-1 - \mathbb{E}[h(b(X), X)]) \\ &= \operatorname{argmax}_{b:\mathcal{X}\rightarrow\mathbb{R}^+} \mathbb{E}[\mathcal{G}_\lambda(b(X), X)],\end{aligned}$$

LAGRANGIAN MULTIPLIER

- ▶ Indicate the strength of the budget constraint
- ▶ The relationship between λ and expected revenue/expense is monotonous
- ▶ The optimal λ can be found by the bisection method using the Training set that depends on the empirical distribution of X

CLOSED-FORM SOLUTION OF LAGRANGIAN RELAXATION

Lemma 2

For any $\lambda \geq 0$, a maximizer of the Lagrangian relaxation takes the form:

$$\forall X \in \mathcal{X}, \tilde{b}_\lambda^{rap}(X) := \arg \max_{b \in \{0, -\frac{\mathbf{W}(\lambda \alpha' e^{(\hat{V}(X)\theta(X) + \lambda e^{\gamma_2} - B)\alpha'})}{\alpha'} + \hat{V}(X)\theta(X) + \lambda e^{\gamma_2}, \infty\}} \mathcal{G}_\lambda(b, X),$$

where \mathbf{W} is the Lambert W -function [3], i.e. the inverse of $f(x) := xe^x$.

EVALUATION METRICS

- ▶ Sharpe ratio [14]
- ▶ (Empirical) Early stop frequency
- ▶ Common KPIs: profit, expense, clicks, impression rate⁴

⁴The probability that advertiser successfully expose the ad to the customers, which is the realized winning rate

RISK CONTROL

► Early stop frequency

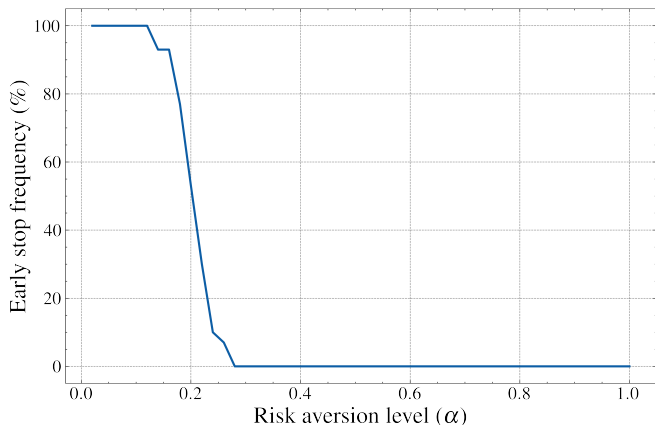

Figure: Empirical Early Stop Frequency under different risk level for the profit model with $B=\bar{B}/32$

COMPARISON

Table: Metrics Results Compared with RMP model when $B=\bar{B}/2$

Metrics	RAP	RNP	RMP-A	RMP-N
Avg. batch clicks	5.600	6.367	3.867	3.700
Avg. batch profit	192574	169873	144471	142193
Avg. batch expense	292121	381178	190200	178052
Avg. impression rate	64.5%	69.6%	41.5%	38.8%
Sharpe ratio of profit	1.083	0.847	0.892	0.922
Early stop frequency	0	100%	0	0

COMPARISON

Table: Metrics Results Compared with RMP model when $B=\bar{B}/32$

Metrics	RAP	RNP	RMP-A	RMP-N
Avg. batch clicks	0.333	1.267	0.433	0.500
Avg. batch profit	20844	85811	30136	19454
Avg. batch expense	8006	23822	7370	23822
Avg. impression rate	7.7%	6.9%	5.0%	7.3%
Sharpe ratio of profit	0.450	0.802	0.487	0.363
Early stop frequency	0	100%	0	100%

CONCLUSION

- ▶ Effective risk control
- ▶ Competitive performance
- ▶ Interpretability & feasibility
